To evaluate perioperative and short-term oncologic outcomes of robotic-assisted renal surgery in comparison to open radical nephrectomy. The study included all patients who underwent robot-assisted laparoscopic radical nephrectomy (RLRN) or open radical nephrectomy (ORN) for treatment of renal cell carcinoma (RCC) at our institution from January 2010 to December 2014. Preoperative, intraoperative, postoperative and outcome data of the first 33 consecutive RLRN were compared to a matched cohort of ORN. Operative parameters, perioperative outcomes, complication rates and short-term oncologic outcomes were assessed. From January 2010 to

The present invention also relates to a data processing system for processing records in this method and to a data processing method for creating printed matter. For accessing records stored in a database, that is to say electronic data, frequently a search using one or more identifiers is used. As a rule, records having a particular identifier are searched for and they are often linked with one another. Then data specified in the records, such as the price of goods in the case of commercial records, or the date of an order, may be read out from the database. If there are a number of records available for access, this can lead to a significant time delay for obtaining the desired data. To avoid this it is possible to search the records in the database for records having predetermined identifiers. However, this often leads to a large number of superfluous records being read out from the database. If records are very much concerned with one another, the search can also yield only a limited number of potential matches because, for example, the value specified by the identifiers is often virtually the same for the various records. The value of the identifier is, for example, the sequential number of the record. The same value often also applies to the other fields of the records. In the case of such records, these identifiers are to be examined individually. They are only suitable for small databases, for example if the database includes only a few thousand or only a

In inter- and intraspecific studies, the use of geometric morphometrics (GM) is increasing to detect within-species traits that may be associated with evolutionary changes. Yet, the GM application in the study of human evolutionary changes is relatively unexplored. One of the topics which attracted increasing interest in paleoanthropological studies is the development of Homo sapiens' face: in comparison to earlier hominins, the anterior profile of the face in modern humans is characterized by a more flat and anterior face and a decreased facial angle, which seems to be caused by a steepening of the lateral convexity. However, before the age of 60, age of establishment of modern morphology, individuals have a rather heterogeneous face shape (intermittent period [IP]). In this study, we investigated the lateral convexity and other orofacial morphological traits of IPs using geometric morphometrics. A sample of 122 craniofacial landmarks was collected from lateral photographs of human skulls preserved in a museum database. In order to estimate the evolution of the IP, we calculated the centroid size and the total length, and in addition, we quantified the differences in facial morphology between IPs and modern adults. We further analyzed, which shape traits account for the differences between IP and adults using an analysis of covariance. The results reveal that the morphological changes in the IP are more pronounced in the upper face (particularly the lower face) rather than in the lower jaw or the sagittal plane. The occlusal plane angle becomes more similar to the adult one and the mean facial angle becomes significantly larger. These findings show that in cases when several specimens in one sample have a recent morphological change like the IP, GM offers the potential to detect this change.- Existence of the
